

# Introduction to Boosting

## Bagging

### Bootstrap Aggregation

DT leads to overfitting (High Variance)

To reduce overfitting, we studied Bagging:- Random forest.

\* Bagging reduces the Variance.

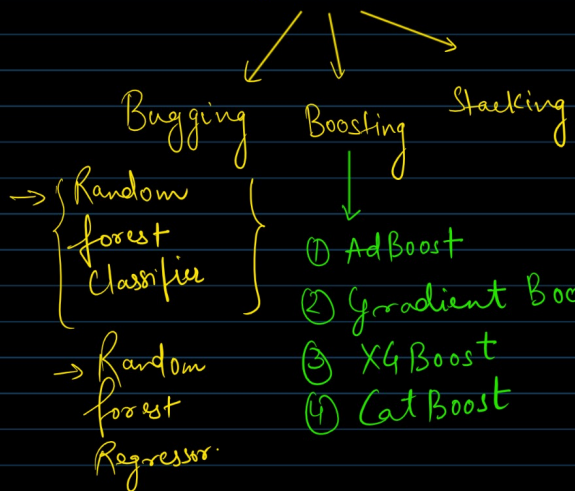

↳ multiple overfitted models combined reduces the Variance.

## Boosting (to Boost | enhance)

Principles:- Build a first model on training dataset and then build a second model to rectify the errors present in the first model. This procedure is continued until and unless the errors are minimised or data is correctly predicted or the numbers of trees you want to build is constructed.

## Ensembles

Bagging: base learner (decision tree)

Boosting: Weak learners (decision tree)

→ for both regression & classification problem.

↓  
because model is  
very simple / Not trained  
properly or has not learned  
much from data.

Analogy  
→ Football → pass  
the ball.  
→ easy to break  
a stick but  
hard to break  
grout / log of  
sticks.

## \* Prediction

### Bagging

- Classification: Voting
- Regression: Average

### Boosting

$M_1 \rightarrow M_2 \rightarrow M_3 \dots M_n$

$$\left\{ \alpha_1(M_1) + \alpha_2(M_2) + \dots + \alpha_n(M_n) \right\}$$

$\alpha_1, \alpha_2 \dots \alpha_n \Rightarrow$  weights

↓  
Strong learner.
